

# Presentation of intermediate results

Agathe L'Hermite

Overleaf

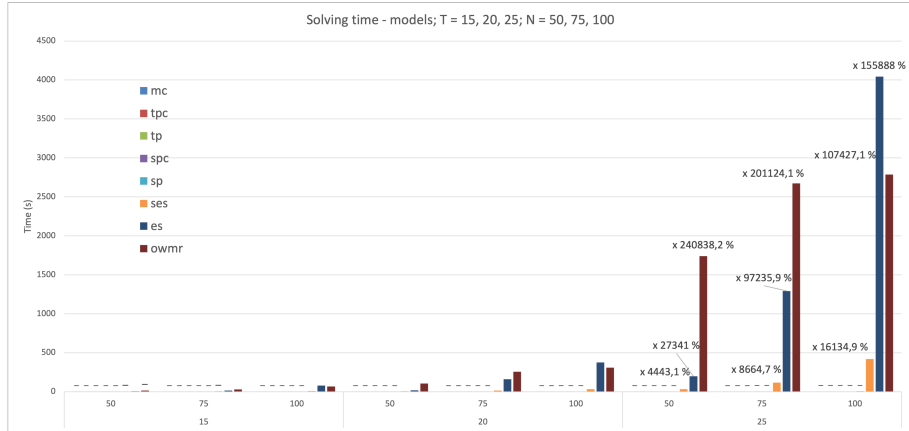

We compare the different formulations proposed by Solyalı and Süral [1] as well as Cunha and Melo [2].

-  Solyalı, O., Süral, H. The one-warehouse multi-retailer problem: reformulation, classification, and computational results, Ann Oper Res 196, 517–541 (2012).
-  Cunha, Jesus O., Melo, Rafael A. On reformulations for the one-warehouse multi-retailer problem. Annals of Operations Research, 99-122 (2016).

# Table of Contents

- 1 No restrictions on ordering periods
- 2 Fixed ordering periods
- 3 Maximum number of periods
- 4 Maximum gap between consecutive orders
- 5 Minimum gap between consecutive orders

# No restrictions on ordering periods - all models

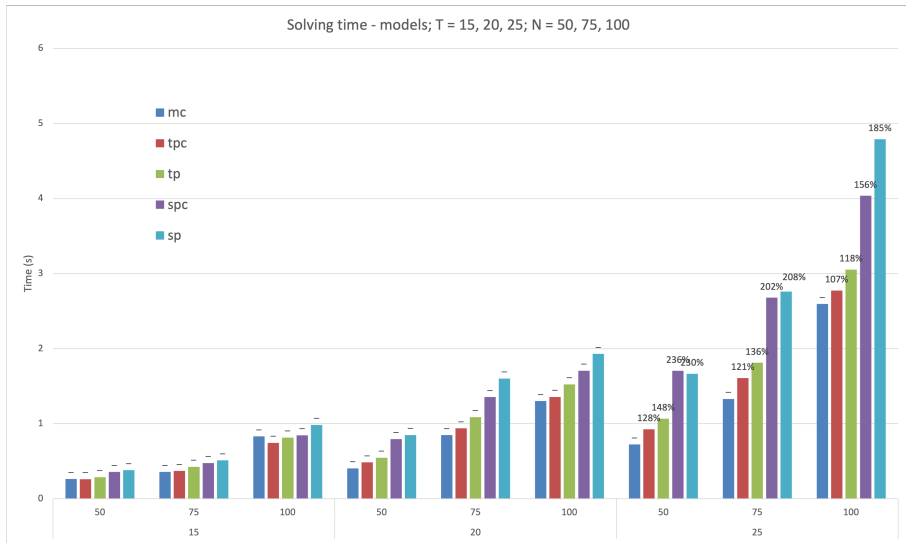

# No restrictions on ordering periods - all models

## Observations

Formulations OWMR, ES and SES are very ineffective compared to other formulations

# No restrictions on ordering periods - 5 fastest models

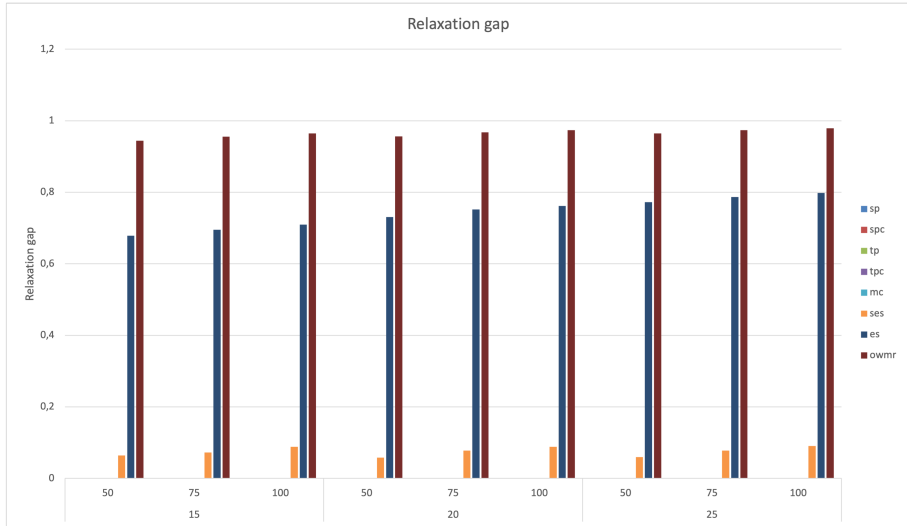

# No restrictions on ordering periods - 5 fastest models

## Observations

MC is our most effective formulation

# No restrictions on ordering periods - relaxation gap

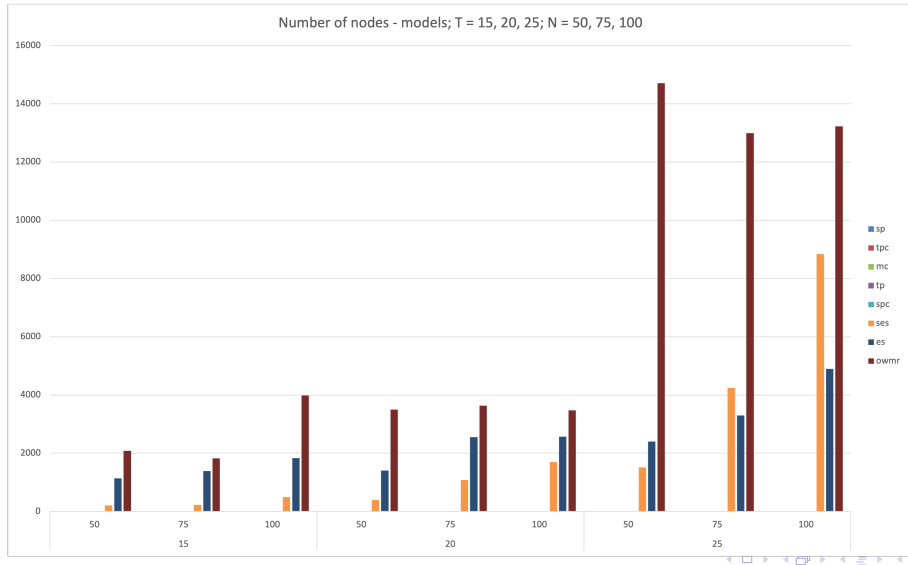

# No restrictions on ordering periods - 5 fastest models

## Observations

ES, SES and OWMR are not very efficient formulations. No significant results for the other models' relaxation gap.

# No restrictions on ordering periods - nodes

# No restrictions on ordering periods - nodes

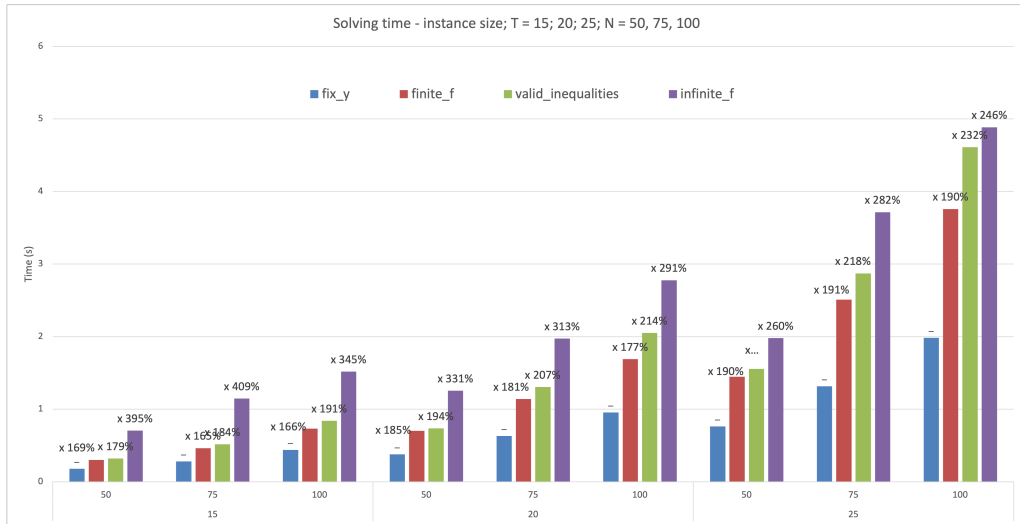

## Observations

OWMR increases more than SES. ES more stable.

# Table of Contents

- 1 No restrictions on ordering periods
- 2 Fixed ordering periods**
- 3 Maximum number of periods
- 4 Maximum gap between consecutive orders
- 5 Minimum gap between consecutive orders

# Fixed ordering periods - methods with size

## Observations

The most effective method is the method fixing the variables  $y$ .

The less effective method is setting the parameters  $f$  to an infinite value, causing to add large parameters in the problem.

Here all the models are mixed, as well as the parameter to decide on the intervals' length.

# Fixed ordering periods - models behaviour

## Observations

The models yield different solving times with the formulation.

ES more balanced.

MC : not efficient with valid inequalities

OWMR most effective with the valid inequalities method.

SP not efficient with valid inequalities.

Transportation-based models become significantly less effective with the infinite method.

Most effective between finite  $f$  and valid inequalities is not clear.

Why?

# Fixed ordering periods - evolution with n

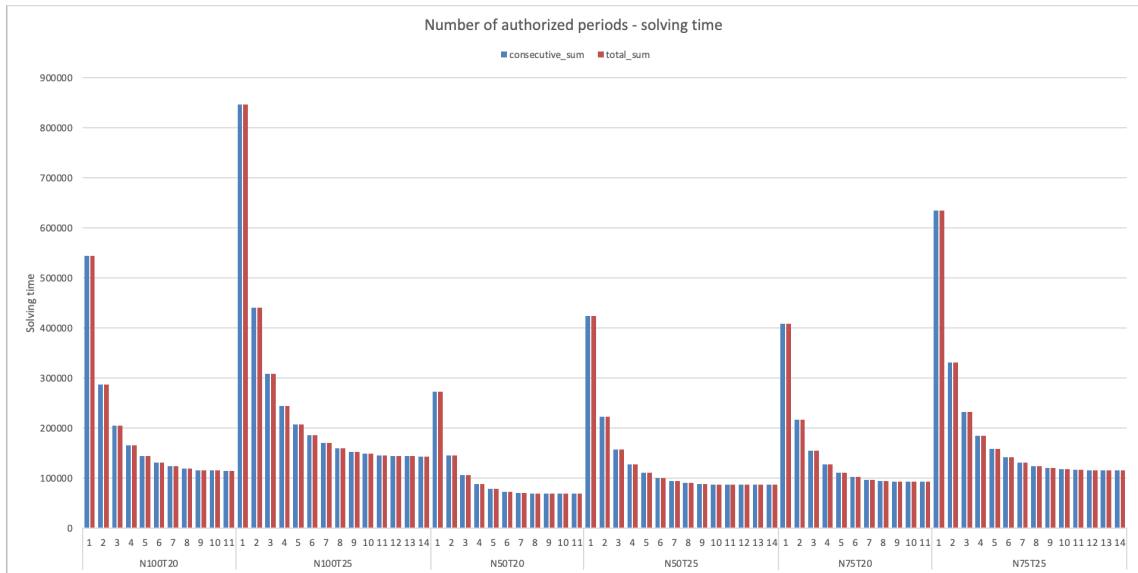

## Observations

The infinite  $f$  method solving time increases when there are more forbidden periods ( + 20 %)  
Other methods decrease ( - 20 %)  
for fix  $y$ : less constraints; finite  $f$  : lower value for  $f$

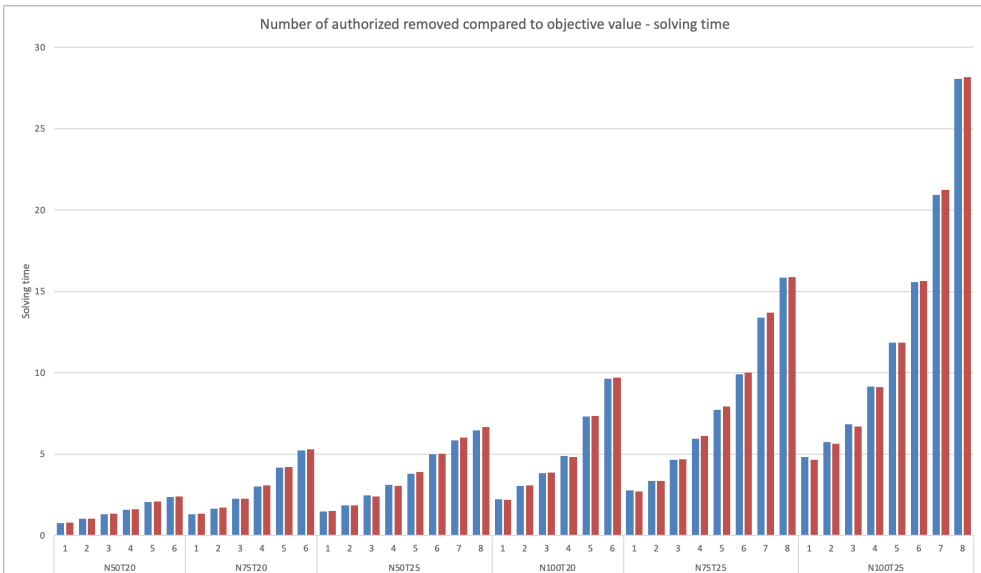

# Table of Contents

- 1 No restrictions on ordering periods
- 2 Fixed ordering periods
- 3 Maximum number of periods**
- 4 Maximum gap between consecutive orders
- 5 Minimum gap between consecutive orders

# Total max - solving time authorized periods

# Total max - relative solving time

# Total max - cost repartition - number of removed periods

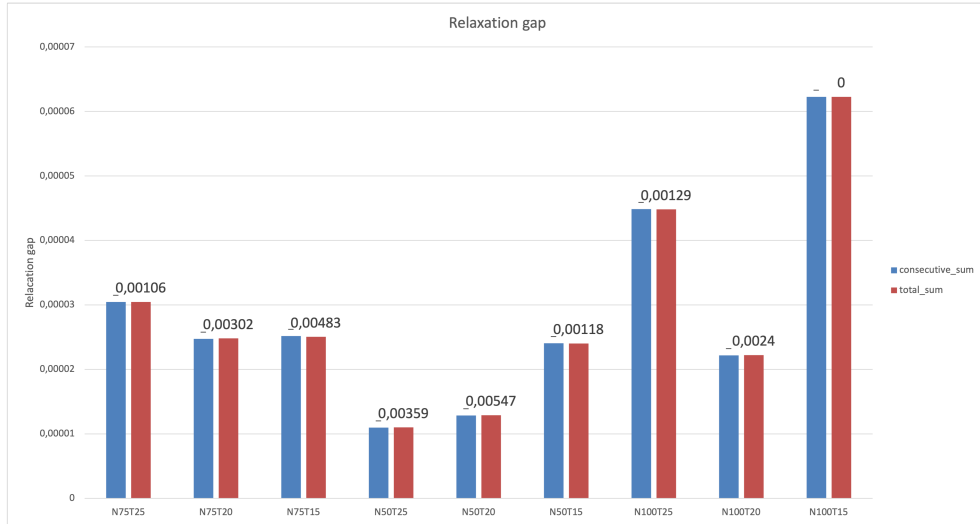

Total max - cost repartition - number of removed periods

## Observations

The holding costs at the warehouse significantly increase.

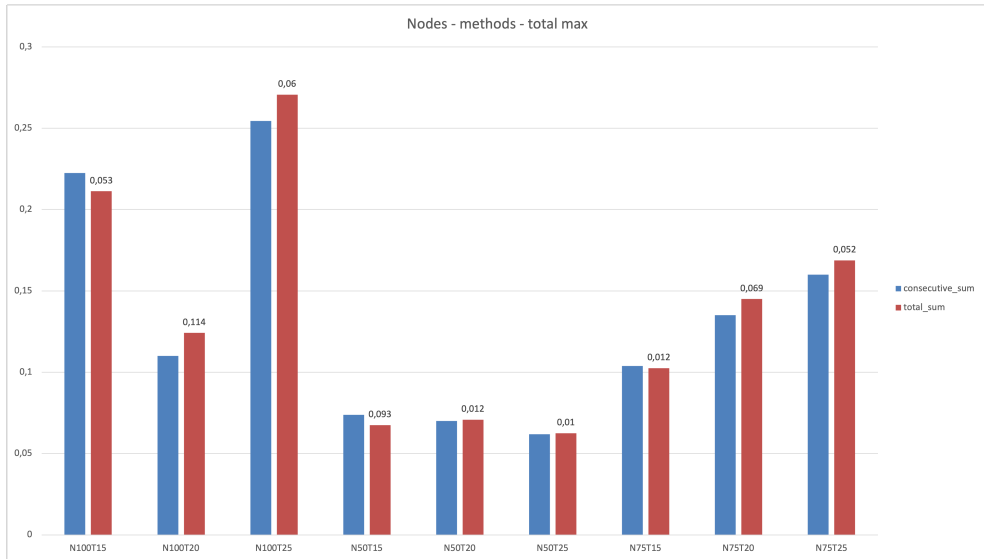

The number of set-ups at retailer decrease : it adapts to the warehouse

# Total max - relaxation gap - tags: relative difference

# Total max - nodes - tags: relative difference

## Observations

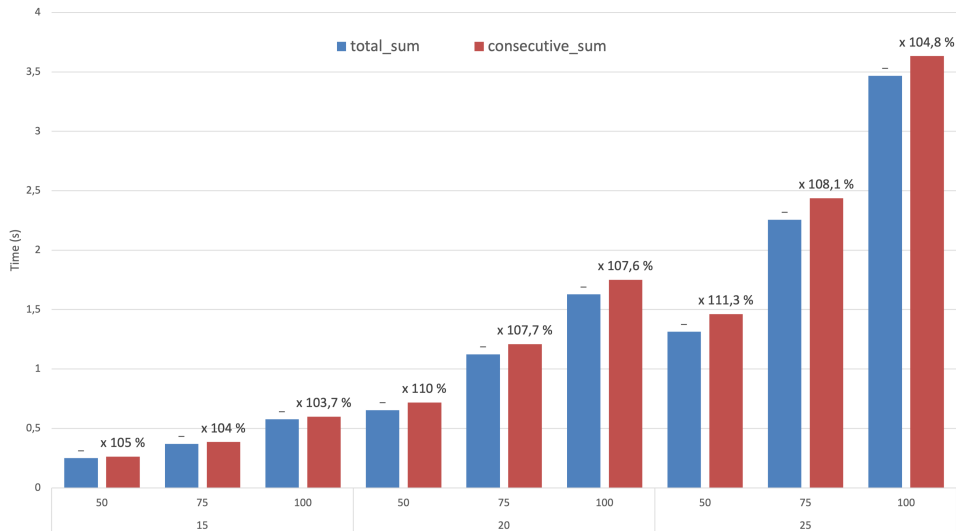

Do the two methods have the same relaxation?

# Table of Contents

- 1 No restrictions on ordering periods
- 2 Fixed ordering periods
- 3 Maximum number of periods
- 4 Maximum gap between consecutive orders**
- 5 Minimum gap between consecutive orders

# Maximum gap - methods with size - 5 models

Solving time - size; T = 15, 20, 25; N = 50, 75, 100

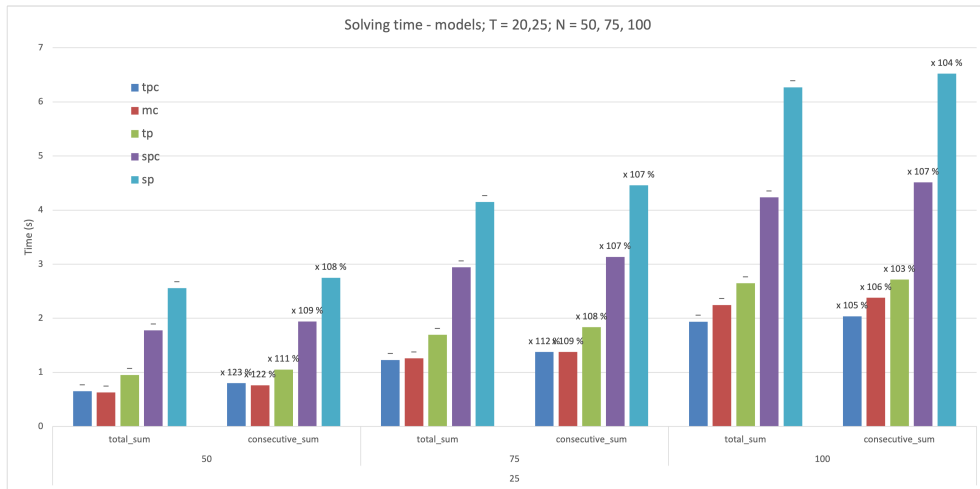

# Maximum gap - methods with size

## Observations

The total sum method is a little more effective than the consecutive sum method.  
Is it really significant?

# Maximum gap - methods with models

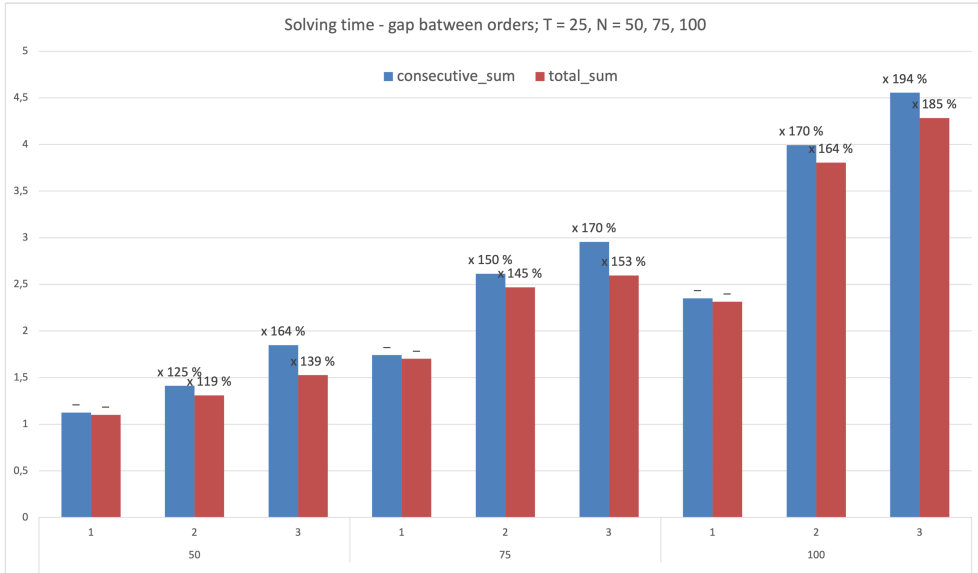

# Maximum gap - methods with models

## Observations

Is there a model that works very badly with a specific method? Same results on all the models.

# Maximum gap - methods with n

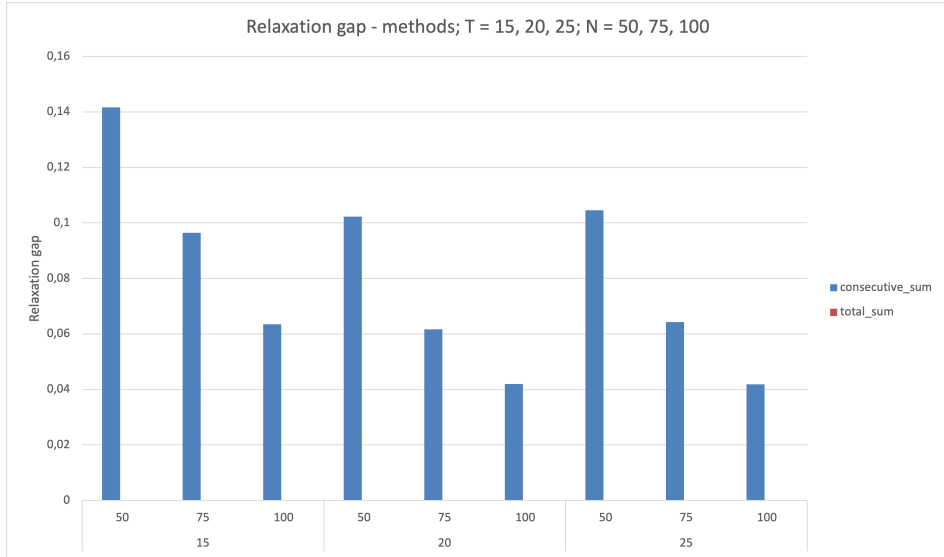

# Maximum gap - methods with $n$

## Observations

The consecutive sum method increases a little more as the mandatory gap increases.

# Maximum gap - relaxation gap

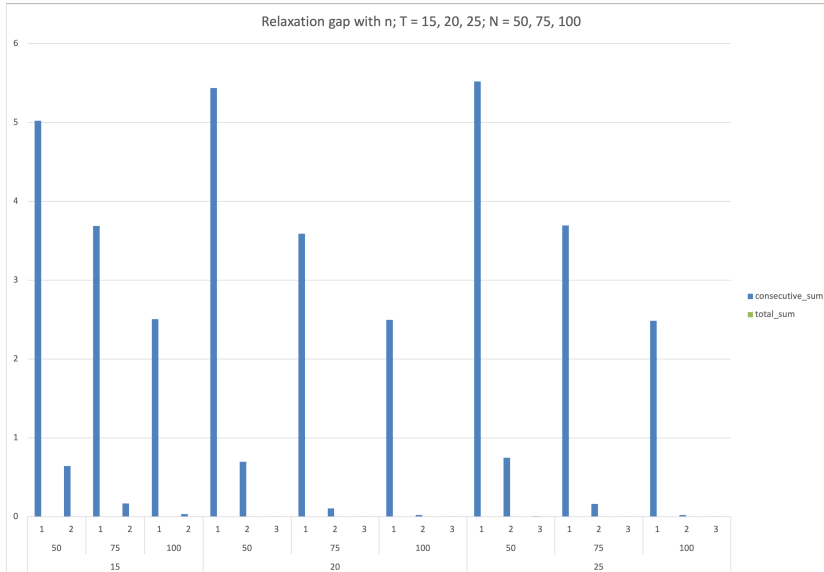

# Maximum gap - relaxation gap

## Observations

Formal proof that consecutive sum is a worse relaxation?

# Maximum gap - relaxation gap and n

# Maximum gap - relaxation gap

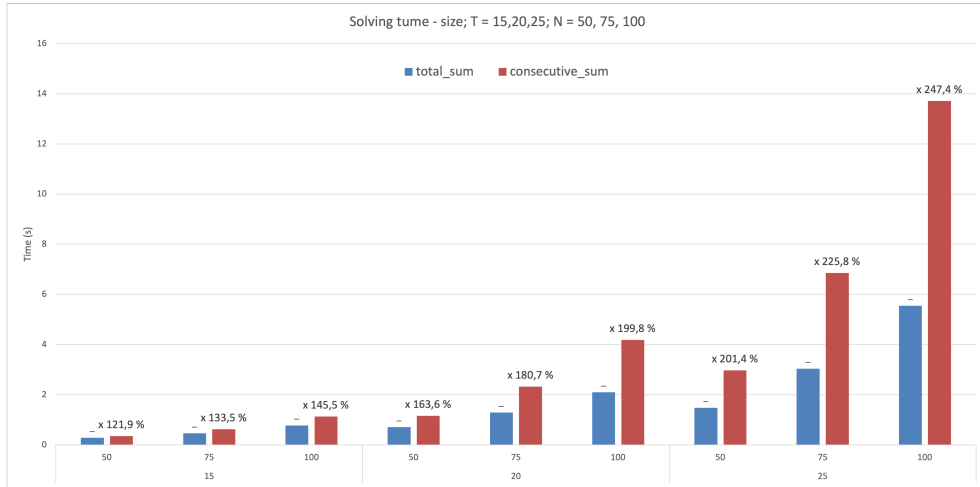

## Observations

Decrease significantly with  $n$

# Table of Contents

- 1 No restrictions on ordering periods
- 2 Fixed ordering periods
- 3 Maximum number of periods
- 4 Maximum gap between consecutive orders
- 5 Minimum gap between consecutive orders

# Minimum gap - methods with size

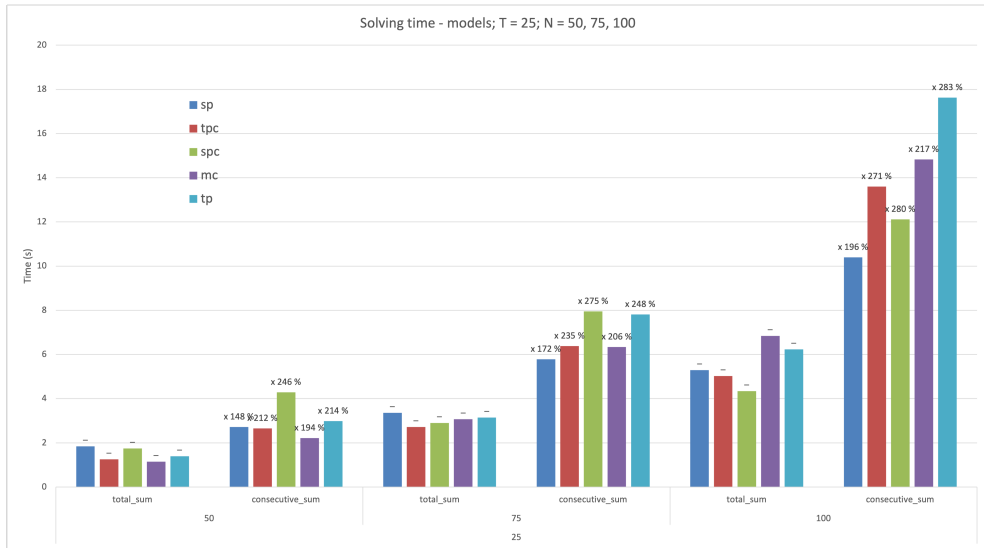

## Observations

The total sum method is far more effective than the consecutive sum method

# Minimum gap - methods with models

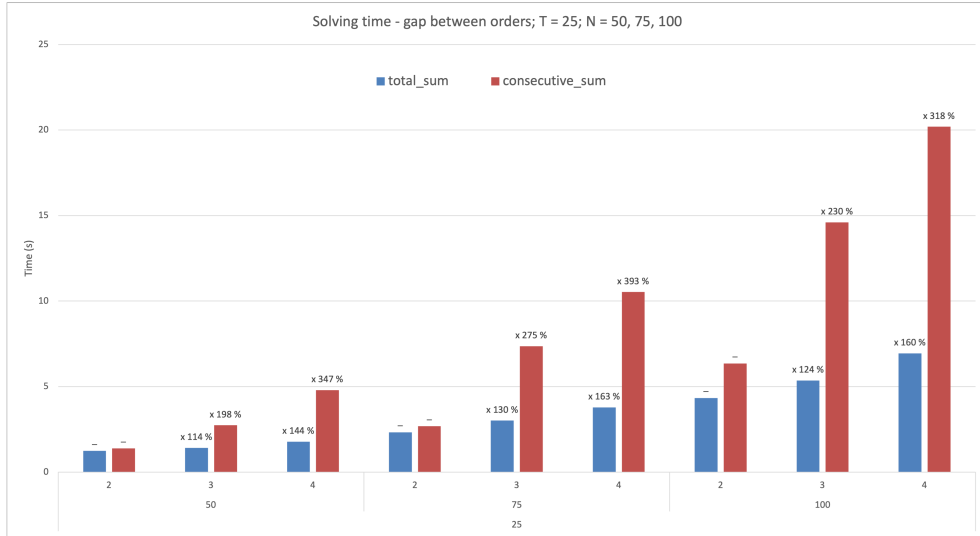

# Minimum gap - methods with models

## Observations

Is there a model that works very badly/well with a specific method? The MC model losses less efficiency between the two methods.

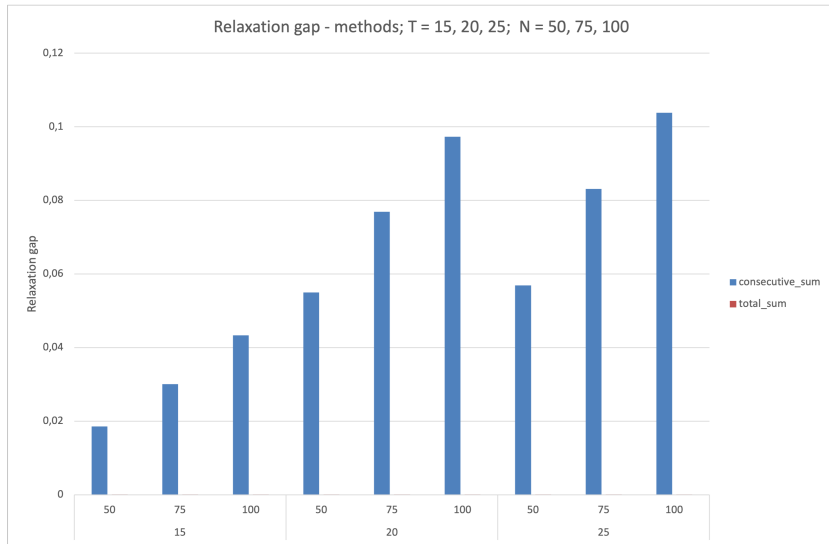

# Minimum gap - methods with n

## Observations

The consecutive sum method solving time increases far more as the mandatory gap increases.

# Minimum gap - relaxation gap

# Minimum gap - relaxation gap

## Observations

same : proof that gap of consecutive sum larger ?

# Minimum gap - nodes

## Observations

attention to the scale
